Dark matter is a form of matter thought to account for approximately 85% of the matter in the universe and about a quarter of its total mass—energy density or about 2.241×10^{-27} kg/m³. Its presence is implied in a variety of astrophysical observations, including gravitational effects that cannot be explained by accepted theories of gravity unless more matter is present than can be seen.

Dark matter - Wikipedia

While there is definitely dark matter in the universe—in the form of CDOs and/or in other forms—the most surprising result of my papers of 2020 is the following: It is quite possible that dark matter or a part of it is represented not by some largely unspecified, undiscovered subatomic particles, but by hydrogen atoms: Namely, by the second flavor, whose existence has already been proven by the analysis of atomic experiments and which could also have astrophysical proof (from the ...

Johns Hopkins University study of 10 billion years of microwaves reveals a warming predicted by dark matter theory. Who says you can't get hotter with age? Researchers from Johns Hopkins University and other institutions have found that, on average, the temperature of galaxy clusters today is 4 million degrees Fahrenheit. That is 10 times hotter than 10 billion years ago, and four times ...

Dark matter haloes can also affect how light bends around astrophysical objects in a process called gravitational lensing. But the signals left in the stellar distributions are weak and prone to confusion with the stars' own motions. Another way to probe the effect of haloes is by looking at the galactic gas it affects.

Researchers have proposed a plethora of dark-matter candidates that explain astrophysical observations while conforming to the results of previous experiments. One of those candidates is the dark-matter boson, a particle that is predicted to interact weakly with ordinary matter.

Physics - Hints of Dark Bosons

The existence of a vast amount of dark matter (DM) in the Universe is supported by many astrophysical and cosmological observations. The latest measurements indicate that approximately a 27% of the Universe energy density is in form of a new type of non-baryonic cold DM.

"A New Dark Force?" | The Daily Galaxy

The nature of dark matter (DM) remains one of the most intriguing unsolved questions of modern physics. Astrophysical and cosmological observations suggest that DM accounts for roughly 27% of the mass-energy of the universe, with dark energy comprising 68% and ordinary baryonic matter as described by the Standard Model accounting for a paltry 5%.

Why Don't Dark Matter Simulations And Observations Match Up?

Dark matter is like the Rome of astronomy, all observations lead to dark matter. The problem is that physicists and astronomers, don't know what it actually is. The observations which support dark matter come from many different independent observations, so it is not just some observational error.
